

Semantics in Space: Traditional semantic maps and Graph Theory

Natalia Levshina © 2017

Semantic maps

- Represent a convenient tool for comparison of semantic and pragmatic functions across languages
- Based on different kinds of data: grammars and typological databases, parallel corpora and experimental data

Main types of semantic maps

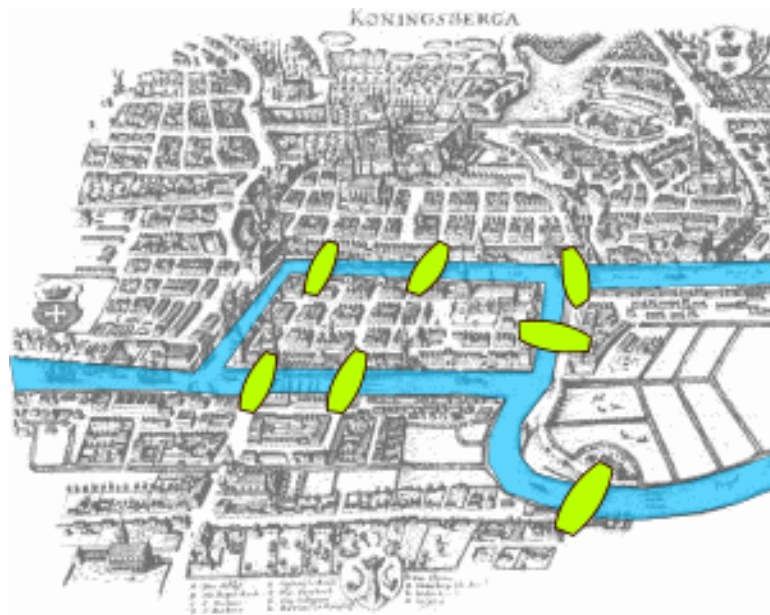

- Connectivity maps, with meanings as nodes (**vertices**) and links (**edges**) between them. Such maps are called **graphs**.
 - Undirected vs. directed (e.g. diachrony)
 - Weighted vs. unweighted
- Probabilistic maps, with distances between objects (e.g. examples from a parallel corpus or stimuli in an experiment)

Graphs are everywhere!

Seven bridges of Königsberg

- Devise a walk through the city that would cross each of the bridges once, and only once.

Graph Theory

- Leonhard Euler (1707 - 1783)

Main types of graphs

- Undirected
- Directed

- Unweighted
- Weighted

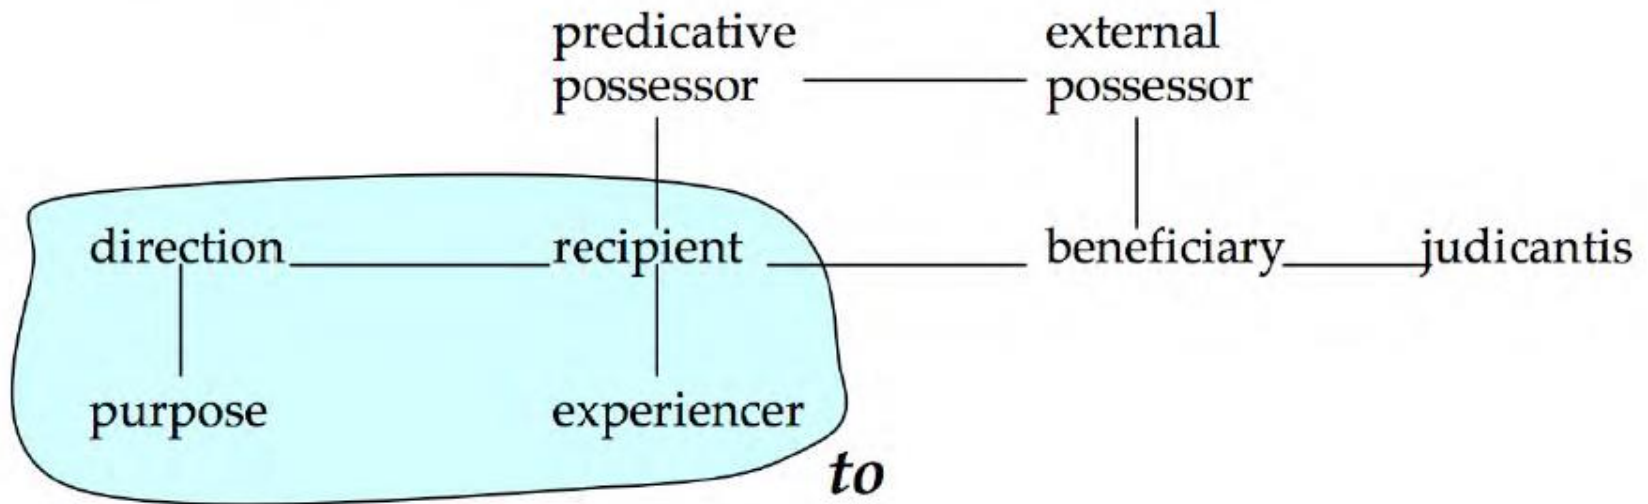

Undirected graphs: marriage

- Mary is John's ex-wife.
- John and Jane are married.
- Peter is single.

Haspelmath 2003: Datives

the English **Dative** preposition *to*

Haspelmath 2003: Datives

the French **Dative** preposition *à*

Main principles of semantic maps

- Nodes: A function is put on a map when there's at least one pair of languages which differ wrt. this function (Haspelmath 2003)
- Links: the principle of connectivity (adjacency/contiguity):
 - if a construction has more than one function, they should be connected (see van der Auwera 2013)

Example 1

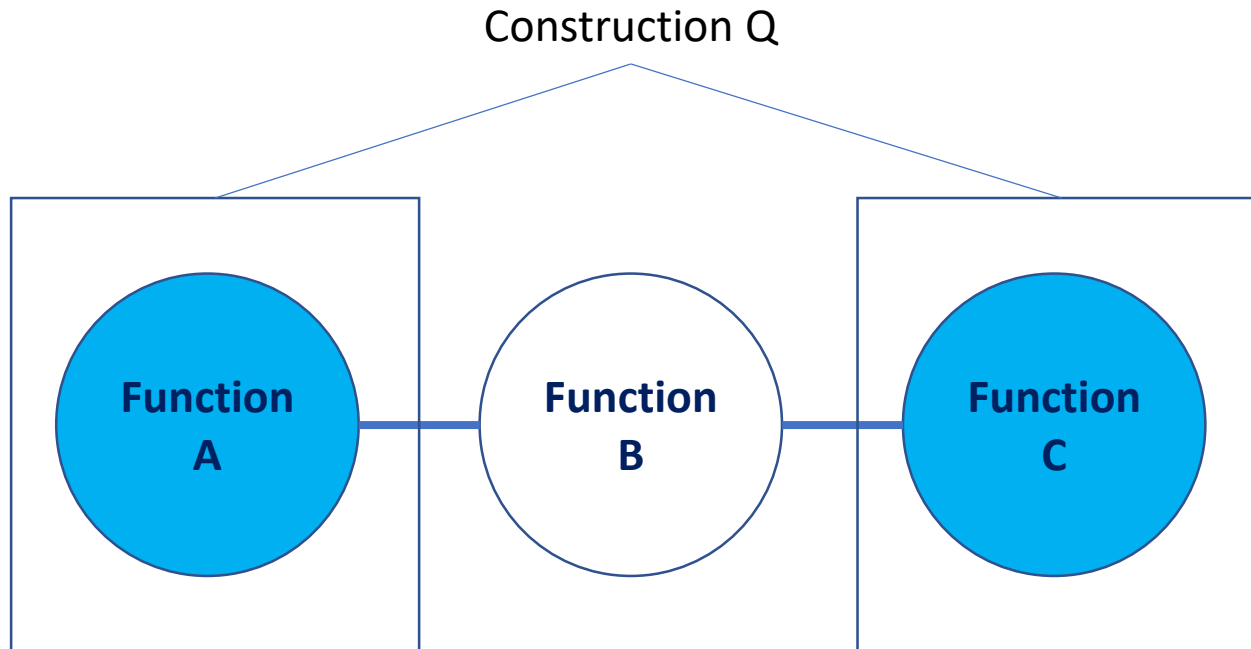

Example 2

Example 3

Example 4

Wrong:
the connectivity principle is not observed!

A fix

Directed graphs: feelings

- Mary loves John.
- John loves Jane.
- Jane loves John.
- And Peter fancies John, too.

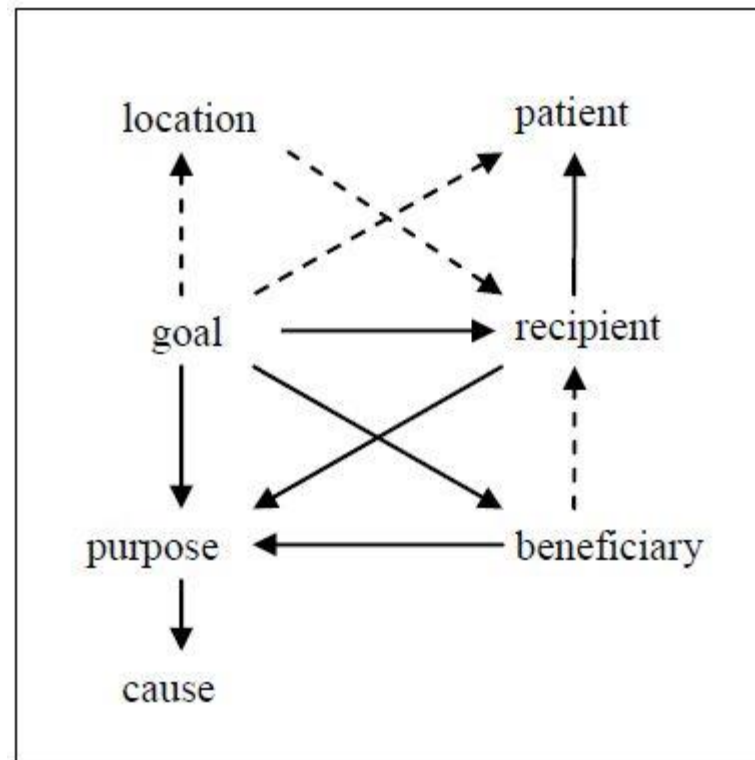

Tense and aspect grams

Bybee et al. (1994)

Goal-Recipient Domain

Narrog (2010)

Weighted graphs: number of pizzas eaten together

- Mary and John have eaten 20 pizzas.
- John and Jane have eaten 10 pizzas.
- Peter and John have eaten 50 pizzas.
- Mary and Peter have eaten 25 pizzas.
- Jane and Mary have eaten 0 pizzas.
- Jane and Peter have eaten 1 pizza.

Case study

Colexification patterns of FOOT

Different methods

- From an adjacency matrix with colexification frequencies
- From a data frame with the list of edges and their weights (colexification frequencies)

Different methods

- From an adjacency matrix with colexification frequencies
- From a data frame with the list of edges and their weights (colexification frequencies)

Adjacency matrix based on CLiCS

```
> foot_am
```

	foot	leg	footprint	wheel	heel
foot	0	71	13	6	7
leg	71	0	7	1	2
footprint	13	7	0	1	0
wheel	6	1	1	0	0
heel	7	2	0	0	0

- This matrix can be regarded as an **adjacency matrix** if we assume that colexification frequencies represent conceptual proximity.

Make a graph from an adjacency matrix

```
> library(igraph)
```

```
> foot_graph <-  
graph_from_adjacency_matrix(foot_am, mode =  
"undirected", weighted = TRUE)
```

```
> plot(foot_graph)
```

Add weights and make prettier

```
> plot(foot_graph, edge.width =  
E(foot_graph)$weight^0.7, edge.color =  
"lightgreen", vertex.label.cex = 1, vertex.size =  
5, vertex.label.color = "black",  
vertex.label.family = "sans", vertex.color =  
"red", vertex.label.dist = 1.5)
```

D3 graphs from igraph graphs

```
> library(networkD3)
> foot_D3 <- igraph_to_networkD3(foot_graph)
> forceNetwork(Links = foot_D3$links, Nodes =
foot_D3$nodes, NodeID = 'name', Group = 'name',
opacity = 0.8, Value = "value", linkDistance =
100, fontSize = 20)
```

Different methods

- From an adjacency matrix with colexification frequencies
- From a data frame with the list of edges and their weights (colexification frequencies)

Data frame with edges and weights

```
> foot_df
```

	from	to	weight
1	foot	leg	71
2	foot	footprint	13
3	foot	wheel	6
4	foot	heel	7
5	leg	footprint	7
6	leg	wheel	1
7	leg	heel	2
8	footprint	wheel	1

Important:

1) The column with weights should be named so explicitly.

2) No zero weights.

Make a graph from a data frame

```
> foot_graph1 <- graph_from_data_frame(foot_df,  
directed = FALSE)  
> plot(foot_graph1)
```

Exercise

- Choose any concept from CLiCS. Find its 5 most frequent colexification neighbours or more (Query > All Links).
- Find the colexification frequencies between all these concepts (Query > Direct Links).
- Create a matrix with those frequencies in R or a data frame with edges and their weights.
- Represent the relationships in a static weighted graph.
- Represent the network in a dynamic weighted D3 graph.

Appendix

R code for making graphs from Haspelmath and Bybee

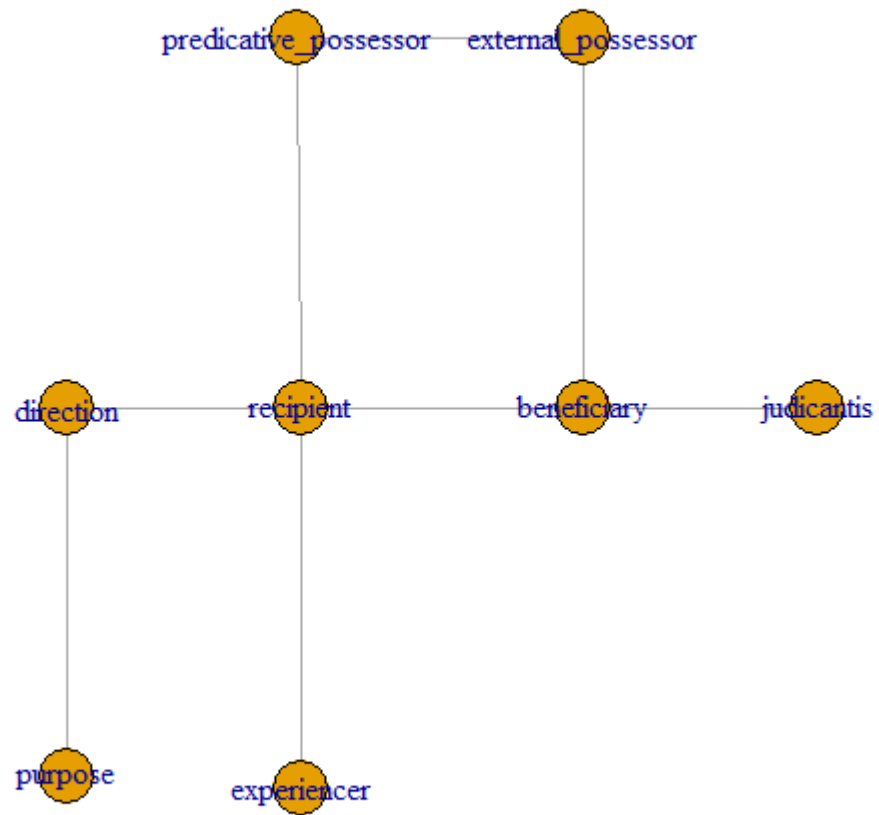

Making undirected graphs with R (datives)

```
> dat_graph <- make_graph(~ purpose - direction -  
recipient - beneficiary - judicantis, experiencer  
- recipient - predicative_possessor -  
external_possessor - beneficiary) #one way of  
providing the edges  
  
> plot(dat_graph)
```

Edit your graph interactively

```
> tkplot(dat_graph) #call the interactive plot  
[1] 1 #ID of the plotting device  
> xy <- tk_coords(1) #save coordinates; change the  
ID, if necessary
```

Plot your graph with new coordinates

```
> plot(dat_graph, layout = xy) #plot with the new  
coordinates
```

```
> plot(dat_graph, layout = xy, vertex.size = 0)  
#no vertex symbols
```

Directed graphs with R (tense and aspect grams)

```
> ta_graph <- make_directed_graph(c("AUX_Part",  
  "Resultative", "Resultative", "Anterior",  
  "Anterior", "Perfective_or_Past", "Finish",  
  "Completive", "Completive", "Anterior",  
  "Movement_from", "Anterior")) #another way of  
entering the data  
  
> plot(ta_graph)
```

Edit the graph interactively and plot it with new coordinates

```
> tkplot(ta_graph)
> tk_coords(2) #or another id of the device
> xy <- tk_coords(2)
> plot(ta_graph, layout = xy)
> plot(ta_graph, layout = xy, vertex.size = 5,
vertex.label.dist = -1.5, edge.arrow.size= 1.2,
vertex.color = "red") #a prettier version
```
